Abstract. I report results on the $X(3872)$ from the Tevatron. Mass and other properties have been studied, with a focus on new results on the dipion mass spectrum in $X \rightarrow J/\psi \pi^+ \pi^-$ decays. Dipions favor interpreting the decay as $J/\psi \rho$, implying even C -parity for the X . Modeling uncertainties do not allow distinguishing between S - and P -wave decays of the $J/\psi \cdot \rho$ mode. Effects of $\rho \cdot \omega$ interference in X decay are also introduced.

Keywords: $X(3872)$, charmonium, exotic mesons

PACS: 14.40.Gx, 13.25.G, 12.39Mk

The charmonium-like $X(3872)$ stands as a major spectroscopic puzzle. Its mass and what is known of its decays makes $c\bar{c}$ assignments problematic. Exotic interpretations have been offered, notably that the X may be a $D^0 \bar{D}^{*0}$ “molecule” [1].

$X(3872) \rightarrow J/\psi \pi^+ \pi^-$ was confirmed by CDF [2] and DØ [3], and is copiously produced at Fermilab’s $\bar{p}p$ collider—albeit with high backgrounds. Mass measurements are compared in Fig. 1, with an average of 3871.2 ± 0.4 MeV/ c^2 . DØ studied other X properties by comparing the fractions of X yield in various types of subsamples to the corresponding fractions for the $\psi(2S)$ [3]. The results for 230 pb $^{-1}$ are summarized in Fig. 1, where the subsamples are the fraction of signal which have: **a**) $p_T(J/\psi \pi\pi) > 15$ GeV, **b**) $|y(J/\psi \pi\pi)| < 1$, **c**) $\cos(\theta_\pi) < 0.4$ (π helicity angle), **d**) proper decay length $ct < 100 \mu\text{m}$, **e**) no tracks with $\Delta R < 0.5$ around the candidate, **f**) $\cos(\theta_\mu) < 0.4$ (μ helicity angle). In all cases the X results are compatible with those of the $\psi(2S)$. CDF used the

The fraction of the yield surviving the listed cut is plotted (see text for descriptions).

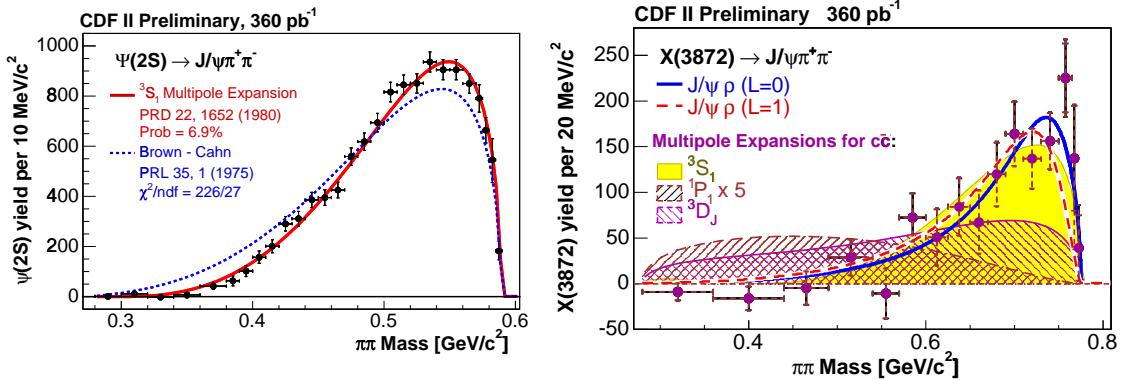

FIGURE 2. **LEFT:** The $\psi(2S)$ dipion mass spectrum with fits of 3S_1 multipole expansion and an older calculation of Brown and Cahn. **RIGHT:** The $X(3872)$ dipion mass spectrum with fits of multipole expansion predictions for C -odd charmonia, and of $X \rightarrow J/\psi\rho$ for $L = 0$ and 1 using a relativistic Breit-Wigner with Blatt-Weisskopf factors ($R_\rho = 0.3$ and $R_X = 1.0$ fm).

proper decay length ct to quantify the fraction of X 's that come from b -hadrons, versus those that are promptly produced. Using 220 pb^{-1} , CDF finds the fraction of X 's from b -decays is $16.1 \pm 4.9 \pm 2.0\%$, in contrast to $28.3 \pm 1.0 \pm 0.7\%$ of $\psi(2S)$'s [4]. The X fraction is somewhat lower than the $\psi(2S)$'s, but within $\sim 2\sigma$. From these perspectives the X is compatible with the $\psi(2S)$. The large X -production at the Tevatron is indicative to some of a charmonium character [5]. Naïvely one expects production of a fragile $D^0\overline{D}^{*0}$ molecule, bound by an MeV or less, to be suppressed. It may, however, be sufficient to accommodate these features if the X merely has a significant $c\bar{c}$ “core.”

Another property is the dipion mass spectrum. If the X has even C -parity, the dipions are (to lowest L) in a 1^{--} isovector state, and dominated by the ρ^0 . An odd- C state produces 0^{++} dipions, for which QCD multipole expansion predictions exist for $c\bar{c}$.

CDF used 360 pb^{-1} ($\sim 1.3k$ X 's) to measure the $\pi\pi$ -spectrum [6, 7]. The sample is divided into $m_{\pi\pi}$ “slices” and fitted for $X(3872)$ and $\psi(2S)$ yields. After modest efficiency corrections, the spectra of Fig. 2 were obtained. The $\psi(2S)$ is a good reference signal and is well modeled by multipole predictions [8]. Also in Fig. 2 are multipole fits to the X for the C -odd $c\bar{c}$ states. The 1P_1 and 3D_J fits are unacceptable. The 3S_1 is an excellent fit to the X , but no 3S_1 $c\bar{c}$ is available for assignment in this mass region.

Earlier this spring CDF provided $J/\psi\rho$ fits using a simple non-relativistic Breit-Wigner sculpted by phase space [6]. Good agreement was obtained (36% probability). About the same time Belle released new dipion data fit with a more sophisticated ρ model [9], which included the effects of angular momentum L for the J/ψ - ρ system. The phase-space factor of the J/ψ momentum in the X rest-frame, k^* , generalizes to $(k^*)^{2L+1}$, thereby turning off the mass spectrum at the upper kinematic limit ($k^* \rightarrow 0$) faster for $L = 1$ than for $L = 0$. Belle obtained a good fit for S -wave decay, but only a 0.1% probability for $L = 1$. Thus, the latter case was strongly disfavored, and in conjunction with angular information, Belle argued for a 1^{++} assignment for the X [9]. The above CDF fit for $J/\psi\rho$ was implicitly for $L = 0$. A CDF fit using Belle's $L = 1$ model also yields 0.1% probability. The implication is, however, not robust.

Breit-Wigner formulations are often modified by Blatt-Weisskopf form factors [10]. The centrifugal modification to $(k^*)^{2L+1}$ tends to be too strong, and for $L = 1$ it is multiplied by $f_{1i}(k^*) \propto (1 + R_i^2 k^{*2})^{-\frac{1}{2}}$, where R_i is a “radius” of meson- i . Specifically, CDF’s $J/\psi\rho$ model is: $dN/dm_{\pi\pi} \propto (k^*)^{2L+1} f_{LX}^2(k^*) |B_\rho|^2$ for angular momentum L . The ρ propagator $B_\rho \propto \sqrt{m_{\pi\pi}\Gamma_\rho(m_{\pi\pi})}/[m_\rho^2 - m_{\pi\pi}^2 - im_\rho\Gamma_\rho(m_{\pi\pi})]$, where $\Gamma_\rho(m_{\pi\pi}) = \Gamma_0 [q^*/q_0^*]^3 \times [m_\rho/m_{\pi\pi}] [f_{1\rho}(q^*)/f_{1\rho}(q_0^*)]^2$, q^* is the π momentum in the $\pi\pi$ rest-frame, and $q_0^* \equiv q^*(m_\rho)$. The ρ parameters m_ρ and Γ_0 are taken from the PDG. The $L = 0$ factor is $f_{0i}(x) = 1$. The f_{1i} factors require two uncertain parameters, R_X and R_ρ . For light mesons, like the ρ , values ~ 0.3 fm are usually found, whereas for charm mesons larger radii ~ 1 fm are often used [11]. Choosing these values for R_ρ and R_X , CDF obtains the fits in Fig. 2 (Right). The $L = 0$ fit has an excellent probability of 55%. While the $L = 1$ probability is not quantitatively as good, it is a respectable 7.7%. This P -wave fit is sensitive to the R_i ’s, whereby the probability can be increased by lowering R_ρ and/or raising R_X . We conclude that flexibility in the fit model can accommodate either L .

Other modeling uncertainties may arise, for example, the effects of ρ - ω interference. Belle reported $X \rightarrow J/\psi\pi^+\pi^-\pi^0$, and interprets it as decay via a virtual ω . As such, they find the ratio of $J/\psi\omega$ to $J/\psi\rho$ branching ratios $\mathcal{R}_{3/2}$ is 1.0 ± 0.5 [12]. Although $\omega \rightarrow \pi^+\pi^-$ is nominally negligible here, its interference effects may not be.

$dN_{2\pi}/dm_{\pi\pi}$ is generalized by replacing $|B_\rho|^2$ with $|A_\rho B_\rho + e^{i\phi} A_\omega B_{\omega 2\pi}|^2$ where A_ρ and A_ω are X -decay amplitudes via ρ and ω , and ϕ is the relative phase. The form for $B_{\omega 2\pi}$ is identical to B_ρ except ρ quantities are replaced by ω ones, including the $\omega \rightarrow \pi\pi$ branching ratio. The ratio $|A_\omega/A_\rho|$ is established by the relationship between $\mathcal{R}_{3/2}$ and the integrals of $dN_{2\pi}/dm_{\pi\pi}$ and $dN_{3\pi}/dm_{3\pi}$ for $X \rightarrow J/\psi\pi^+\pi^-\pi^0$, where the latter is $\propto |A_\omega B_{\omega 3\pi}|^2$. The $B_{\omega 3\pi}$ follows $B_{\omega 2\pi}$ except the numerator contains $\Gamma_{\omega 3\pi}(m)$. While $\Gamma_{\omega 2\pi}(m)$ follows $\Gamma_\rho(m)$, a different form for $\Gamma_{\omega 3\pi}(m)$ is adapted from the SND experiment studying $e^+e^- \rightarrow \pi^+\pi^-\pi^0$ [13]. They model $\omega \rightarrow \pi^+\pi^-\pi^0$ as virtual $\rho\pi$ decays and use the ω matrix-element $|\vec{q}_{\pi^+} \times \vec{q}_{\pi^-}|^2$, where $\vec{q}_{\pi^{+/-}}$ are $\pi^{+/-}$ momenta.

The integral of $dN_{2\pi}/dm_{\pi\pi}$ depends upon the phase, which is *a priori* unknown. As an illustration, $|A_\omega/A_\rho|$ is determined assuming that ϕ arises completely from ρ - ω mixing, i.e. $\phi = 95^\circ$ [14]. The $dN_{2\pi}/dm_{2\pi}$ decomposes into three parts: “pure” ρ and ω terms, and an interference cross-term. In this model with $\mathcal{R}_{3/2} = 1.0$, these fractions are, respectively, 71.0, 6.2, and 22.8% for S -wave decay, and 67.4, 8.7, 23.9% for P -wave. Fits with these fractions imposed are shown in Fig. 3 (Left). The S -wave probability has declined as the model peaks too much at high mass, but is still very good at 19%. Increasing the amount of high masses with interference improves the P -wave fit to 53%. The $L = 1$ fit is sensitive to ϕ and R_X as is seen in the inset of Fig. 3. The dependence on R_ρ is relatively weak for both L . The overall picture from these fits is insensitive to the $\pm 1\sigma$ span of $\mathcal{R}_{3/2}$, as is seen in Fig. 3 (Right).

In summary, properties of $X(3872) \rightarrow J/\psi\pi^+\pi^-$ studied at the Tevatron are quite similar to those of the $\psi(2S)$. There is no viable C -odd charmonium assignment according to QCD multipole expansion fits to the $\pi\pi$ -mass spectrum. Decay to $J/\psi\rho$ provides good fits, irrespective of the $c\bar{c}$ structure. This implies the X is C -even, in-line with Belle’s report of $X \rightarrow J/\psi\gamma$ [12]. The effects of ρ - ω interference are introduced,

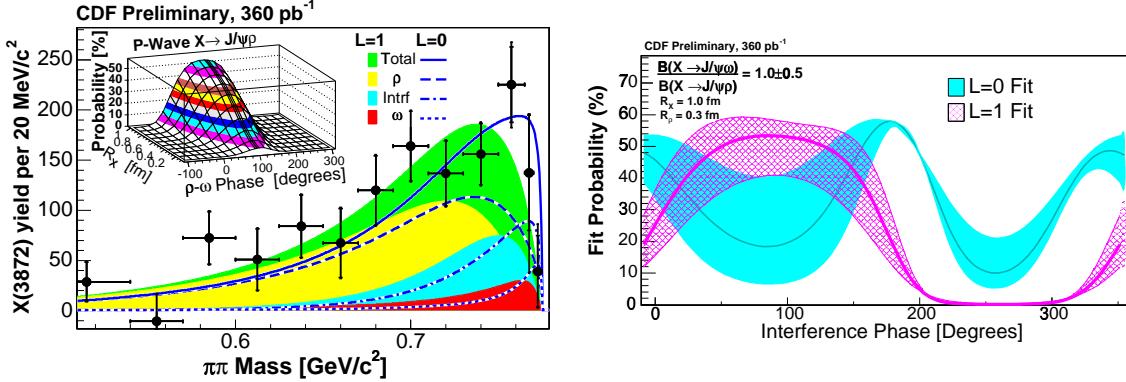

FIGURE 3. **LEFT:** Blow-up of the dipion spectrum with $J/\psi\rho$ fits for $L = 0$ (lines) and 1 (shaded) including $\rho\omega$ interference with 95° phase and sub-components set by $\mathcal{R}_{3/2} = 1.0$. The decomposition into ρ , interference, and ω terms is given. The inset shows $L = 1$ fit probabilities as a function of ϕ and R_X in 5% contours. **RIGHT:** $J/\psi\rho$ fit probabilities for $L = 0$ (shaded) and 1 (hatched) as a function of phase. The bands span the $\pm 1\sigma$ range of $\mathcal{R}_{3/2}$.

and can be quite important. This type of $\rho\omega$ modeling highlights that $\mathcal{R}_{3/2} \sim 1$ implies the *intrinsic* amplitude for $X \rightarrow J/\psi\rho$ is actually significantly suppressed relative to $J/\psi\omega$ by virtue of the much greater phase space for $J/\psi\rho$ decay over $J/\psi\omega$. Given the modeling uncertainties governing the tails of the Breit-Wigners—especially if $\rho\omega$ interference is in play—the CDF spectrum can be well described by $J/\psi\rho$ decay of either $L = 0$ or 1: such as from C -even charmonia (e.g. 1^{++} or 2^{-+}) or from a 1^{++} exotic as preferred for a $D^0\bar{D}^{*0}$ molecule.
